Benchmark Prep FS — Phase 3 Verification: Agent Prompt

Version · v1.0.0 — 2026-10-24

For · The coding agent on Charlie's Windows PC (repo cloned, `gh` authenticated as crieck2010, Phase 1 release artifacts present).

Use · Attach the Phase 3 pack PDF, then paste the prompt verbatim. Charlie does the Console upload himself; these jobs make sure what he uploads — and what Play delivers — is exactly what Phase 1 built.

Attach with the prompt (PDF):

1. `2026-10-24_fs-phase3-internal-track-pack_v1.0.0.pdf` — the phase pack (carry-overs are Jobs 0–1's authority).

TASK: Phase 3 verification for Benchmark Prep FS, in four jobs. Charlie performs the Play Console steps himself (attached pack). You verify the ground under them. Do not change app code or dependencies in any job.

JOB 0 — Turn on GitHub Pages (the privacy URL is dead). docs/privacy.html is committed, but Pages was never enabled: the Pages API and the public URL both 404. Run: gh api -X POST repos/crieck2010/FS-Exam-Prep-Mobile-App/pages -f source='{"branch":"main","path":"/docs"}' Then poll https://crieck2010.github.io/FS-Exam-Prep-Mobile-App/privacy.html until it returns HTTP 200 with the policy page (Pages can take a few minutes). If the gh call errors, STOP and report the error verbatim — Charlie will use repo Settings > Pages instead. Report the confirmed live URL.

JOB 1 — The Firebase verdict (carried over from Phase 2). Inspect the MERGED AndroidManifest of the release build (app/build/intermediates after assembleRelease, or APK Analyzer on the release APK/AAB) and report every Firebase component present: FirebaseInitProvider, component-discovery services, AppCheck providers, analytics/crash services — quoting the exact manifest entries. Grep app source for FirebaseApp / Firebase.ai / AppCheck

initialization calls and report hits or their absence. Verdict line, exactly one of: "VERDICT: no Firebase component initializes" "VERDICT: initializes — " Do NOT remove dependencies; Charlie decides the diet after your verdict.

JOB 2 — Verify the upload artifact before Charlie uploads it. For the Phase 1 AAB (app-release.aab): - Confirm package and version from the artifact itself (bundletool dump manifest, or APK Analyzer): package must be com.crieck.prep.fs, versionName 0.9.0, versionCode 2. - Confirm it is signed: keytool -printcert -jarfile on the AAB (no password needed) — report the signer certificate's SHA-256 fingerprint and owner line. If any value differs from the above, STOP and report before Charlie uploads anything.

JOB 3 — After rollout: prove the phone runs the Play build. Once Charlie has installed from the internal track opt-in link: adb shell dumpsys package com.crieck.prep.fs Report versionCode, versionName, and the installer field — installer must read com.android.vending (the Play Store), which proves the device is running the store-delivered, Google-re-signed build and not the Phase 1 sideload. Also re-capture the five listing screenshots from this build at native resolution (Today, a quiz question, the mock exam, Learn, Progress) into listing-assets/screenshots/ named 01-today.png ... 05-progress.png, and commit them: "docs: listing screenshots from Play build".

REPORT: Job 0 live URL (or the verbatim error); Job 1 verdict with manifest evidence; Job 2 artifact values + signer fingerprint; Job 3 dumpsys values + screenshot commit hash. Push only the Job 3 screenshot commit, after Charlie confirms.

After the run — Charlie's checks

1. Job 1's verdict drives the Data safety form (pack, carry-over 2) — that form must be complete before the internal release rolls out.
2. If Job 2 stops the line, nothing uploads until the artifact mismatch is understood — bring it back to Muse.
3. Muse verifies the screenshot commit and the live privacy URL on the word.
