Benchmark Prep FS — Dependency Diet: AI Studio Prompt

Version · v1.0.0 — 2026-10-24

For · Google AI Studio Build project syncing to `crieck2010/FS-Exam-Prep-Mobile-App`, base commit `0e17bb0`

Why now · Roadmap Phase 5 item, pulled forward into the Play identity-verification wait. Removes the unused Firebase/networking scaffold so the app's "collects no data" position is structural, not evidentiary.

Attachments · **None needed** — this prompt is self-contained; all findings are quoted inline.

Evidence this is safe (Phase 3, Job 1 — merged-manifest scan): source contains zero Firebase/Retrofit/OkHttp initialization or usage; there is no google-services.json; the Firebase components in the merged manifest come solely from these libraries' own AAR manifests. The app loads its question bank from bundled assets via org.json and persists progress in Room — neither is touched by this diet.

TASK: Dependency diet for Benchmark Prep FS. Remove the unused Firebase and networking scaffold from app/build.gradle.kts, and bump the version. Nothing else changes.

CONTEXT (verified by audit): the source code never imports or calls Firebase, Retrofit, OkHttp, or Moshi — the bank loads via org.json from assets, persistence is Room. These dependencies are leftovers from the original project scaffold. The merged manifest's FirebaseInitProvider and AppCheck/Firebase-AI registrars exist only because these libraries ship them.

REMOVE exactly these active lines from app/build.gradle.kts:
implementation(platform(libs.firebase.bom))
implementation(libs.firebase.ai)
implementation(libs.firebase.appcheck.recaptcha)
implementation(libs.firebase.appcheck.debug)

implementation(libs.converter.moshi) implementation(libs.retrofit) implementation(libs.okhttp) implementation(libs.logging.interceptor) And the google-services wiring, which exists only for Firebase: - the plugin alias line: alias(libs.plugins.google.services) - the import at the top: import com.google.gms.googleservices.GoogleServicesPlugin.MissingGoogleServicesStrategy - the config block: googleServices { missingGoogleServicesStrategy = MissingGoogleServicesStrategy.WARN }

MOSHI — conditional: also remove implementation(libs.moshi.kotlin) "ksp"(libs.moshi.kotlin.codegen) ONLY if a source search for "import com.squareup.moshi" across app/src returns zero hits. If there are ANY hits, leave both Moshi lines in place and report the files instead.

BEFORE REMOVING ANYTHING: search app/src for imports of com.google.firebase, retrofit2, okhttp3. If any file imports them, STOP, remove nothing, and report the files — the audit says there are none, and a contradiction means the audit is stale, not that you should improvise.

VERSION (same file, defaultConfig): versionCode 2 -> 3 versionName "0.9.0" -> "0.9.1" Change nothing else in defaultConfig (applicationId stays com.crieck.prep.fs).

SCOPE FENCE: - app/build.gradle.kts is the ONLY file that changes. - Do NOT touch gradle/libs.versions.toml (unused catalog entries are inert), any source file, assets, metadata.json, or the signingConfigs blocks. - Room, Compose, coroutines, lifecycle, and all test dependencies stay exactly as they are. - No new dependencies.

REPORT BACK: 1. The complete diff of app/build.gradle.kts. 2. The source-search results (firebase / retrofit2 / okhttp3 / moshi import hits, or "zero hits" for each). 3. Whether the Moshi pair was removed or kept, and why. 4. Confirmation that no other file changed.

After the run — the chain

1. Muse re-audits the push (diff = the listed lines only).
2. Charlie's PC: rebuild (`bundleRelease` + `assembleRelease`, Phase 1 Step 5) and the quick smoke pass (S1/S4/S10) — the diet build becomes 0.9.1 (3), the version that gets uploaded when

Console verification clears.

3. Data safety's "no data collected" is thereafter true by construction; the Firebase caveat closes permanently.
